What This Document Is For

Standard primary school practice conditions candidates to write answers directly in their workbooks, with no concept of a separate answer sheet. This assumption is procedurally fatal at Queen Elizabeth's School.

At QE Boys, the machine-marked GL Assessment OMR sheet is the only document that determines a candidate's Standardised Age Score. A flawless answer written in the booklet yields zero marks if the corresponding OMR row is left blank, filled incorrectly, or misaligned. This document deconstructs every procedural risk and provides the mechanical protocols to neutralise them.

> ***"The OMR sheet is the examination. Everything else is preparation."***

01 Automated Assessment Mechanics

Machine Marked

At Queen Elizabeth's School, the examination is machine-marked in its entirety by GL Assessment optical scanners. Human examiners do not evaluate the papers.

THE ASSESSMENT METRIC

The physical question booklet is not evaluated. Any annotations, working out, or answers written in the booklet are discarded. The candidate's Standardised Age Score (SAS) is calculated exclusively from the data inputted onto the separate Optical Mark Recognition (OMR) answer sheet.

The Implication: Correct mathematical deduction yields zero marks if the candidate fails to transfer the corresponding letter to the OMR sheet accurately. Precision in data transfer is a strict procedural requirement.

THE BOOKLET

The question booklet contains all stimulus material, word problems, and answer options. Annotations and working out written here are for the candidate's use only. They are not seen by examiners and carry no marks.

THE OMR SHEET

The separate Optical Mark Recognition sheet is the sole source of mark data. Each row corresponds to one question. The candidate shades the lettered box for their chosen answer. This sheet is fed through an optical scanner after the examination.

02 Answer Misalignment Risks

Potential mistakes

Due to the 50-minute time constraint, candidates frequently omit highly complex questions to preserve time. This creates a critical risk: sequential misalignment.

B. THE ERROR MECHANISM

If a candidate skips a question in the test booklet (e.g. Question 24) but fails to skip the corresponding row on the separate OMR sheet, they will input their intended answer for Question 25 into Row 24.

The Consequence: From that specific point forward, every subsequent answer on the remainder of the paper will be offset by one row. This desynchronisation renders all following answers incorrect, severely diminishing the candidate's final standardised score regardless of their actual academic capability.

The Misalignment Cascade

A single skipped row on the OMR sheet does not produce one wrong answer. It produces every answer from that point forward being wrong. The table below shows the cascade effect of a skip at Question 24.

OMR Row	Booklet Question Intended	Status
Row 24	Question 24 (skipped)	Blank / Placeholder
Row 25	Question 25	Correct row
Row 26	Question 26 answer entered in Row 25	Offset by one
Row 27	Question 27 answer entered in Row 26	Offset by one
Row 28	Continues for all remaining rows	Offset by one

03 Tactical Execution: Two-Point Physical Tracking

How to prevent this

Relying solely on visual tracking between a densely formatted GL booklet and an OMR sheet leads to transfer errors. Candidates must use a physical tracking method to ensure synchronisation.

The Four-Step Transfer Protocol

This protocol must be executed for every single question, without exception. It takes under three seconds per transfer and eliminates the misalignment risk entirely.

Step	Action Required	Status
Step 1	The Booklet Anchor: Place non-dominant index finger directly on the question number in the printed booklet. Finger remains stationary until data transfer is complete.	**Protocol Step**
Step 2	Visual Transition: Determine the answer, then direct attention to the OMR sheet while keeping the non-dominant finger anchored on the booklet.	**Protocol Step**
Step 3	Row Verification: Using the pencil in the dominant hand, physically verify that the row number on the OMR sheet matches the anchored question number in the booklet.	**Protocol Step**
Step 4	Data Transfer: Heavily shade the designated rectangular box, then move the non-dominant index finger down to anchor the next question number in the booklet.	**Protocol Step**

04 Managing Omitted Questions: The Placeholder Protocol

Sealing the Row

Leaving an OMR row blank is the primary cause of sequential misalignment. Because the QE Boys GL Assessment uses zero negative marking, leaving a row blank serves no strategic purpose.

THE PLACEHOLDER PROTOCOL

If a candidate decides to omit a question in the booklet to save time, they must immediately input a predetermined placeholder answer (e.g. Option C) into the corresponding OMR row.

Booklet Notation: The candidate places a clear, distinct mark (e.g. an asterisk) next to the omitted question in the physical booklet. If surplus time remains at the end of the 50-minute allocation, the candidate returns to the marked question, erases the placeholder on the OMR sheet, and attempts a complete calculation.

WHY IT PRESERVES ALIGNMENT

Inputting a placeholder seals the row immediately. The numerical sequence of all subsequent questions is preserved. No cascade desynchronization can occur from that point forward, regardless of how many questions are skipped.

WHY IT SECURES MARKS

Because QE Boys GL Assessment uses zero negative marking, a placeholder answer carries no penalty. A randomly placed Option C secures a 20% statistical probability of gaining a correct mark. A blank row secures 0%.

05 Practice Standardisation: Mandating OMR Usage

Eliminate the Shortcut

Standard primary school practice conditions candidates to write or circle answers directly in their workbooks. This practice must be eliminated during QE Boys preparation.

THE SIMULATION REQUIREMENT

Candidates must immediately cease recording final answers within their practice workbooks. Executing tests without an OMR sheet artificially inflates practice scores by removing the time expenditure and procedural risk required for data transfer.

Implementation: Every timed mock examination and practice drill must be completed using separate GL Assessment formatted OMR sheets. The procedural mechanics of locating a row, verifying the number, and shading the box must become automatic, standardised practice prior to the September examination.

WITHOUT OMR PRACTICE

Practice scores are inflated. Time is not spent on transfer mechanics. Row verification is not practiced. The candidate walks into the examination hall encountering the OMR process under pressure for the first time.

WITH OMR PRACTICE

Practice scores are accurate and diagnostic. Transfer mechanics become automatic. Row verification takes under three seconds. The candidate executes the protocol under examination conditions without conscious effort.

1

The Two-Point Tracking Protocol

Before initiating any data transfer, place the non-dominant index finger on the question number in the booklet. Do not move this finger until the OMR row has been verified and shaded.

Note: This protocol takes under three seconds per question. Over a 80-question paper, it adds less than four minutes and prevents the single most catastrophic error type in the examination.

2

The Placeholder Protocol

Never leave an OMR row blank. The instant a question is skipped in the booklet, immediately shade a placeholder in the corresponding OMR row and mark the booklet with an asterisk.

Note: These two protocols together eliminate the misalignment risk entirely and convert every skipped question from a 0% mark probability to a 20% mark probability. That margin alone separates a waitlist result from an unconditional offer.
